Geologic Core Repository Testbed

The geologic data catalog for the Savannah River Site (SRS) includes more than 1,200 soil and rock cores archived at the Geological Core Repository. The contents of the core repository constitute an unrivaled collection of unconsolidated sediments deposited in fluvial, deltaic and shallow marine environments along the emergent southeastern Atlantic Coastal Plain during the Cretaceous and Tertiary time periods. The repository also contains many samples of buried Paleozoic bedrock and Triassic basin-fill sequences, rocks that are rarely sampled in this region.

This Geologic Core Repository can serve as a testbed whereby the primary uses of unconsolidated sediment cores can be accessed to improve ones understanding of sediment heterogeneity and physical properties; delineate boundaries of various stratigraphic units; predict groundwater movement and the behavior of contaminants; and add geotechnical rigor to facility siting and foundation design. The bedrock cores are a record of continental rifting and tectonism along the southeastern U.S. continental margin.

Attributes

- High-resolution sampling of the entire upper Atlantic Coastal Plain stratigraphic sequence, including sediments of the Floridan aquifer, an important source of drinking water for five southeastern states
- Many cores in the Santee Formation, which directly influences facility siting, design and foundation stability
- Age constraints and movement history for basement faulting

Impact

- Tangible archive of 60-plus years of subsurface investigations at SRS and surrounding region
- Ready access to sediments that compose regional aquifers and aquitards
- Important record of pre-remediation conditions at RCRA/CERCLA sites
- Availability of geologic samples to support geo-modeling, performance assessments, facility siting, waste disposition and remedial decision-making
