Boron-structured Nano-proportional Counters for Neutron Detection

Scientists at the Savannah River National Laboratory (SRNL) have explored the use of nanotechnology to improve the design of gas-filled proportional counters (PC). The new nano-detector design will require a much lower operating voltage, a smaller power supply, enhanced portability, increased sensitivity to radiation, and improved detection efficiency.

Background
SRNL has investigated an alternative to conventionally constructed gas-filled PCs using a boron-coated nanostructured array affixed on an insulating substrate to replace the traditional PC wire anode. Use of nanostructures can reduce the required operating voltage by more than 100 times compared to traditional PCs due to the inherently high electrical fields associated with nanoscale anodes. Furthermore, the new model will eliminate the need for scarce resources, making it a more economically feasible design for the future; coating the arrays with layers of boron-10 allows for the detection of neutrons without the use of Helium-3, an isotope in considerably dwindling supply.

How it works
Nanomaterials have garnered a lot of interest due to their unique physical, chemical, and most notably, electrical properties. It has been shown that the ability to generate very high electric fields around conductive nanostructures at low voltages can be attributed to their nanoscale alone. As a result, gas multiplication occurs at significantly lowered potentials, facilitating higher sensitivity and detection efficiency, shorter count times, high electric fields with low applied voltage, smaller, more portable detector and power supply, no need for use of scarce materials, and alpha, beta, gamma and neutron detection capability. U.S. Patent 9,075,148 B2
Technology transfer

The Savannah River National Laboratory (SRNL) is the U.S. Department of Energy's (DOE) applied research and development laboratory at the Savannah River Site (SRS).

With its wide spectrum and expertise in areas such as homeland security, hydrogen technology, materials, sensors, and environmental science, SRNL’s cutting edge technology delivers high dividends to its customers.

The management and operating contractor for SRS and SRNL is Savannah River Nuclear Solutions, LLC. SRNS is responsible for transferring its technologies to the private sector so that these technologies may have the collateral benefit of enhancing U.S. economic competitiveness.

Stage of development

This technology is in early stage research and development with ongoing testing underway. Two types of nanoscale anodes (boron-doped Si pillars and carbon fibers) have been fabricated and tested. Early modeling and laboratory studies have demonstrated that there is a considerable reduction in voltage required to reach the proportional counting region, but detector design has not been optimized. Nano-PCs can potentially be used as detectors for illicit trafficking of radioactive material, dosimeters, tritium gas monitors, handheld radiation detectors, and environmental sensors. A patent has been filed with the U. S. Patent and Trademark Office.

Partnering opportunities

SRNS invites interested companies with proven capabilities in this area of expertise to develop commercial applications for this process or product under a cooperative research and development agreement or licensing agreement. Interested companies will be requested to submit a business plan setting forth company qualifications, strategies, activities, and milestones for commercializing this invention. Qualifications should include past experience at bringing similar products to market, reasonable schedule for product launch, sufficient manufacturing capacity, established distribution networks, and evidence of sufficient financial resources for product development and launch.
